Abstract

Background: Integrons have a well-established role in the dissemination of resistance among Gram-negative pathogens and are thus a useful marker of antibiotic resistance. Shigellae are noteworthy for their multiple drug resistance, having gradually acquired resistance to most widely used and inexpensive antimicrobial drugs.

Methodology: A total of 32 Shigella strains belonging to serotypes flexneri, dysenteriae, and boydii 20, a new Shigella serovar, resistant to at least four antibiotics were analyzed by molecular techniques.

Results: Class 1 integrons were the most prevalent (92.8%); class 2 integrons were found in 16 strains (57.1%). Fifty percent of the strains harboured both class 1 and 2 integrons (intII and intI genes); this combination of integrase genes was most prevalent in S. boydii 20 and S. dysenteriae strains. The class 1 integrons detected contained dfr and aadA cassettes, alone or in combination (dfrA15/aadA1, orfX), or a typical cassette array with an insertion sequence (oxa30-aadA1-IS1). For class 2 integrons, we detected either the same cassettes as those found in Tn7 (dfrA1sat1-aadA1-orfX) or truncated class 2 integrons without aadA1 or orfX. The int genes were absent from all class 2 integrons.

The distribution of integrons among RAPD profiles and serotypes revealed a clonal spread of integrons into serotypes and a transfer of integrons between different serotypes.

Conclusions: The detection of integrons in a new Shigella serovar, in addition with a high integron prevalence among Shigella strains, confirms the propensity of shigellae to acquire and disseminate resistance determinants.

Key words: multi-resistant Shigella; integrons; dfr

Introduction

Shigellosis, which is primarily a disease of resource-poor populations, is an important cause of morbidity and mortality among people of all ages living in communities lacking adequate sanitation and safe water. Children under five years old in developing countries are particularly at risk. An estimated 160 million cases and 1.1 million deaths per year are due to shigellosis [1]. Shigella flexneri is the most prevalent serotype in Africa [2-4]. Shigellae are noteworthy for their multiple drug resistance, having gradually acquired resistance to most widely used and inexpensive antimicrobial drugs [5-8].

Mobile genetic elements such as plasmids and transposons are involved in the spread of resistance, together with genomic islands and integrons. Integrons are genetic elements that, by site-specific recombination, can integrate gene cassettes, usually antibiotic resistance genes [9]. Class 1 and 2 are the most frequent in Gram-negative bacteria [10]. The structure of class 1 integron includes 5’ and 3’ conserved segments and a variable region containing gene cassettes. Most previously described class 2 integrons contain the same array of four gene cassettes, three antibiotic resistance gene cassettes (dfrA1, sat and aadA1), conferring resistance to trimethoprim, streptothricin, and spectinomycin/streptomycin, respectively), and the orfX cassette of unknown function. Class 2 integrons have been described in transposon Tn7 and its derivatives, and their 3’ segment contains five tns genes involved in transposon movements [11]. The movement of cassettes are catalyzed by site-specific recombination; cassette mobility results in the dissemination of resistance genes.

Integrons have a well-established role in the dissemination of resistance among Gram-
negative pathogens and are thus a useful marker of antibiotic resistance [12]. Trimethoprim is widely used to treat several infectious diseases in Senegal, in combination with sulfonamides. As trimethoprim resistance determinants are often found in gene cassettes, we examined the prevalence of integrons in Senegalese Shigella isolates.

Materials and methods

Bacterial isolates

A total of thirty-two Shigella strains belonging to serotypes flexneri (N = 14), dysenteriae (N = 13), and Shigella boydii 20 serovar nov. (N = 5) isolated from adults with diarrhoea at a teaching hospital and an urban general hospital in Dakar, Senegal, were included in the study.

Antimicrobial susceptibility

Antibiotic susceptibility was tested with the disk diffusion method on Mueller-Hinton agar (Becton Dickinson Cokeysville, Md), and antibiotics were those used for Enterobacteriaceae, as recommended by the Clinical Laboratories Standards Institute (www.clsi.org).

DNA extraction

Total DNA was extracted with the QIamp DNA minikit (Qiagen, S.A, Courtaboeuf, France).

Integron detection

The strains were screened by PCR for class 1, 2 and 3 integrons with the primers described above [13,14,15]. The 50-µl PCR reaction mix consisted of Taq polymerase buffer, 1.5 mM MgCl₂, 200 µM deoxynucleotide triphosphates, 50 pmol of each primer (Isoprim, Toulouse, France), 1 U of Taq, and 25 ng of DNA were amplified in a thermal cycler (Perkin-Elmer 2400, Applied Biosystems).

PCR with primers orf4 (5'-CAAACTATCACGTTCAAGTCTGTT-3') and sulI (5'-GTCCGACATCCACGACGTCTGATC-3') were used to detect the 3' segment usually found in class 1 integrons [15]. PCR amplification of the class 1 integron cassette array used primers 5'CS (5'-GGCATCCGGACCGATGCAGATTGT-3'), aadA3 (5'-GAATGATGTCTGACAAAC-3') located in the aadA1 gene cassette (this study), and orfX2 (5'-AGATACATGATCTCTCAGGCC-3') [16].

To characterize the 3’ segment of class 2 integrons, amplification was performed using primers int2CS2 (5'-TACCTGTTCGTGCCGTATCT-3’) and int7S (5'-TGCCCTGCGTAAGCGGTGTTGGCGGACA-3’) [15].

DNA sequencing

Purified PCR products were sequenced on an ABI Prism automatic sequencer, as recommended by the manufacturers; the nucleotide sequences were compared online at the National Center for Biotechnology Information (NCBI) website.

Conjugation experiments

Mating experiments were conducted in Luria-Bertani broth with the nalidixic acid-resistant E. coli strain C1a as recipient. Transconjugants were selected on Luria-Bertani agar plates containing nalidixic acid (50 µg/ml), and trimethoprim (100 µg/ml) or ampicillin (100 µg/ml). All transconjugants were screened for intI1 and intI2 by PCR.

Random amplified polymorphic DNA analysis (RAPD)

RAPD was performed with primers A4 (5’-TGCCCGGAC-3’) and A5 (5’-GCGGAGCT-3’) [15] (Bioprobe Systems, Montreuil sous bois, France). Strains were considered non-identical if their RAPD patterns differed by at least two bands.

Results

Antibiotic resistance

All the strains were resistant to at least four of the following antibiotics: ampicillin, ticarcillin, tetracycline, trimethoprim, sulfamethoxazole, streptomycin, and chloramphenicol (Table 1).

Int genes

Twenty-eight (87.5%) of the 32 strains contained at least one integron, and 26 of these 28 strains contained at least one class 1 integron. The intI2 gene was detected in 16 strains, either alone (2 strains of S. flexneri) or together with intI1 (14 strains). The intI1 and intI2 genes were found together in all S. boydii 20 isolates, and in 9 of the 14 S. dysenteriae isolates. No class 3 integrons were detected.

Cassette arrays

In 3’ segment-containing class 1 integrons, the gene cassettes arrays were characterized by PCR with primers 5’CS and 3’CS and by sequencing the amplification products. The strains yielded amplicons ranging from 0.7 kb to 1.8 kb. Four different cassette arrays with one (dfrA5, dfrA15) or two cassettes (dfrA15-aadA1, dfrA1-aadA2) were characterized (Table 1). The 14 strains lacking the 3’ segment were resistant to streptomycin and spectinomycin, owing to the presence of aadA gene cassettes, of which aadA1 was most prevalent. To determine the cassette arrays of these strains, amplification was performed with primers 5’CS and aadA3 yielding a PCR product of 1.5 kb. Sequencing of this product showed the presence of two cassettes, oxa30 and aadA1. Dubois et al. described Shigella strains containing a class 1 integron in which these two cassettes were followed by the insertion sequence ISI. Successful amplification with primers AaA3 and 1s1b (5’-GTGAACGACTATGGCGACGC-3’), located within ISI [17], confirmed that the genetic environment was the same as that described by Dubois et al. [18].

The class 2 integrons of our strains were heterogenous; two S. flexneri strains harbouring exclusively class 2 integrons had a classical organization with the same four cassettes as those found in Tn7, dfrA1, sat, aadA1 and orfX. Either The aadA1 or the orfX cassette was lacking in all strains containing both class 1 and 2 integrons (Table 1).

Transfer of antibiotic resistance and genetic location of integrons

Resistance to ampicillin, ticarcillin, streptomycin, tetracycline, sulfamethoxazole, trimethoprim, excepted chloramphenicol for one strain of Shigella dysenteriae was transferred simultaneously from all Shigella strains harbouring class 1 integrons with cassette arrays (dfrA15, dfrA1-aadA1, dfrA1-aadA2). Conjugation experiments were unsuccessful for strains harbouring unusual class 1 and 2 integrons supporting the chromosomal location of these integrons. Strains harbouring the classical class 1 and 2 integrons yielded transconjugants on trimethoprim suggesting their plasmidic location.

Distribution of integrons among RAPD types and serotypes

Six RAPD profiles were identified, three in Shigella dysenteriae (A, B, C), two in Shigella flexneri (D, E), and one in Shigella boydii 20 (F) (Table 1). Two Shigella dysenteriae strains...
belonging to the B profile did not contain integrons. All *Shigella dysenteriae* and the majority of *Shigella flexneri* strains (11/12) harbouring integrons showed a unique RAPD profile but had a different integron carriage except *Shigella boydii* 20 strains which showed a unique profile with the same integron content (Table 1). These data revealed a clonal spread of integrons among serotypes and a transfer of integrons between different serotypes.

**Discussion**

Antibiotic resistance is common in *Shigella* spp. [7,19,4,20]. In Senegal, multiple resistance to ampicillin, sulfamethoxazole, trimethoprim and tetracycline is related to the intensive first-line use of these antibiotics to treat diarrhoeal illnesses and other infectious diseases. Here we found that 87.5% of 32 *Shigella* strains isolated in Senegal contained at least one integron. This marked dissemination of integrons among *Shigella* spp is partly linked to the propensity of this genus to acquire plasmids, as multidrug resistance integrons are usually plasmid-borne [18]. In this study, class 1 integrons were the most prevalent, in keeping with the results of other studies of *Shigella* isolates [18]. In contrast, integron prevalence is very low in other parts of the world [20,21,22]. We found class 2 integrons in half the 32 strains studied here. Other studies have shown that class 2 integrons are more prevalent in industrialized and/or emerging countries [23,24,25]. Among shigellae, class 2 integrons tend to be associated with *Shigella sonnei* [26,20,27,28]. We detected class 1 and 2 integrons in *S. dysenteriae*, *S. flexneri* and in the new serovar of *S. boydii* 20. The latter was first isolated in Canada from patients who had recently travelled to Cuba, Ethiopia, India, Guatemala or Mexico [28]. In Senegal, this serovar was identified between July and September 2000.

Class 1 integrons were highly diverse, with five different integrons harbouring a *dfr* cassette, alone or associated with *aadA1*. Furthermore, all class 2 integrons detected contained the *dfrA1* cassette and 8 out of 16 also contained *aadA1* cassette. Our results thus showed that trimethoprim and streptomycin/spectinomycin resistant gene cassettes were highly encountered in Senegalese *Shigella* isolates. In sub-Saharan Africa, trimethoprim is widely used, in combination with sulfonamides, to treat diarrhoeal illnesses and urinary tract infections as well as to prevent opportunistic infections in HIV-infected and malarial patients [29,30]. Streptomycin is intensively used to treat tuberculosis, in combination with other drugs. The high prevalence of *dfr* and *aadA1* gene cassettes in integron-containing *Shigella* strains may thus be related to the use of these antibiotics. However, the *dfr* and *aadA* cassettes are also very common in integrons harboured by other *Enterobacteriaceae* species isolated from patients in industrialized countries [20,21]. In a previous study in Senegal we also found a high prevalence of *dfr* and *aadA* cassettes in integron-containing enteroaggregative and enteroinvasive *Escherichia coli* (*E. coli*) strains [31]. Horizontal transfer could readily occur between *E. coli* and *Shigella*, which are both enteric pathogens. Indeed, we successfully obtained transconjugants with *dfr*-containing strains. These two studies showing a high prevalence of *dfr*-containing integrons in enteric pathogens strongly challenge the use of trimethoprim in Senegal.

We detected the unusual class 1 integron with partial or total deletion of the 3’ segment, as previously described in *Shigella dysenteriae* and *Shigella flexneri* [26,18]. In our strains this atypical class 1 integron was found either alone or associated with a class 2 integron lacking the *aadA1* or *orfX* cassette. This type of integron was associated to multiple resistance (as shown in Table 1) and confirm the role of integron in antibio-resistant. Otherwise, the deletion of the *aadA1* cassette could result from intI1 integrase-catalyse co-integrate formation between a class 1 and 2 integron or a possible RecA-dependent homologous recombination between two copies of the same cassette in both classes of integron [32]. Integron carriage was unrelated to the RAPD profile in *Shigella dysenteriae* and *Shigella flexneri*, whereas *Shigella boydii* 20 strains had a unique profile with the same integron content, indicating clonal spread. Previous studies also found similar patterns for *S. boydii* serotype 20 by using pulsed-field gel electrophoresis and ribotyping, and inferred that this serotype could be homogeneous [28,33].

The detection of integrons in a new *Shigella* serovar, in addition with high integron prevalence among *Shigella* strains, confirms the propensity of shigellae to acquire and disseminate resistance determinants.

The presence of integrons in *Shigella* may have important clinical implications, as multiple gene cassettes could be captured by such strains easily leading to multidrug resistance, even to broad-spectrum antibiotics such as third-generation cephalosporins and quinolones.
